

ABSTRACT

An electronic device has a main body, a flip attached to the main body and multiple input interfaces. A first input interface is disposed on the main body of the electronic device. Second and third input interfaces are disposed on apposing sides of the flip. The flip covers at least a part of the first input interface when the flip is in a closed position. The flip is rotatable so that either the second or third interface can be selectively used when the flip is in the closed position.
